## I. INTRODUCTION

This work has come about from a **partnership** between the Faculty of Sciences of Oporto University and the sprayers' company Rocha, SA to calibrate the mass flow from the dual-disc centrifugal fertiliser spreader model KC RD 1000.

It has the following main **objectives**:

- determination of mass flow uniformity between spreader conduits;
- comparison of the “commercial version’s” fertiliser flow with the fertiliser flow of the ‘preliminary version’ of the KC RD 1000 spreader;
- determination of fertiliser density technical tables ( $\text{kg ha}^{-1}$ ) for different factorial combinations of fertiliser flow, rate of advance and working width.

## II. FERTILISER FLOW TESTS

The calibration tests were carried out with two types of fertiliser:

- Ammoniacal nitrogen fertiliser with 27% nitrogen content which we call “Nitro”.
- Ternary Complex fertiliser which we call “Tern”.

All the calibration tests were carried out with the spreader activated by TDF under a standardised 540 r.p.m. regime.

The fertiliser flow ( $\text{kg min}^{-1}$ ) was determined independently for each of the spreader conduits (left conduit and right conduit) (see figure 1). 3 repetitions were carried out for each of the spreader flow scale positions.

## III. RESULTS

### 1. COMPARISON OF FERTILISER FLOWS BETWEEN CONDUITS

Figure 2 sets out the estimated results and statistical tests for comparing the fertiliser flow between conduits (right vs left) of the Rocha spreader.

It can be seen that the confidence intervals for the mean between conduits coincide and the probability associated with the test  $t_{Student}$  for paired samples and it always exceeds 5%. Hence, we can conclude that there are no statistically significant differences between the mass flow of both conduits.

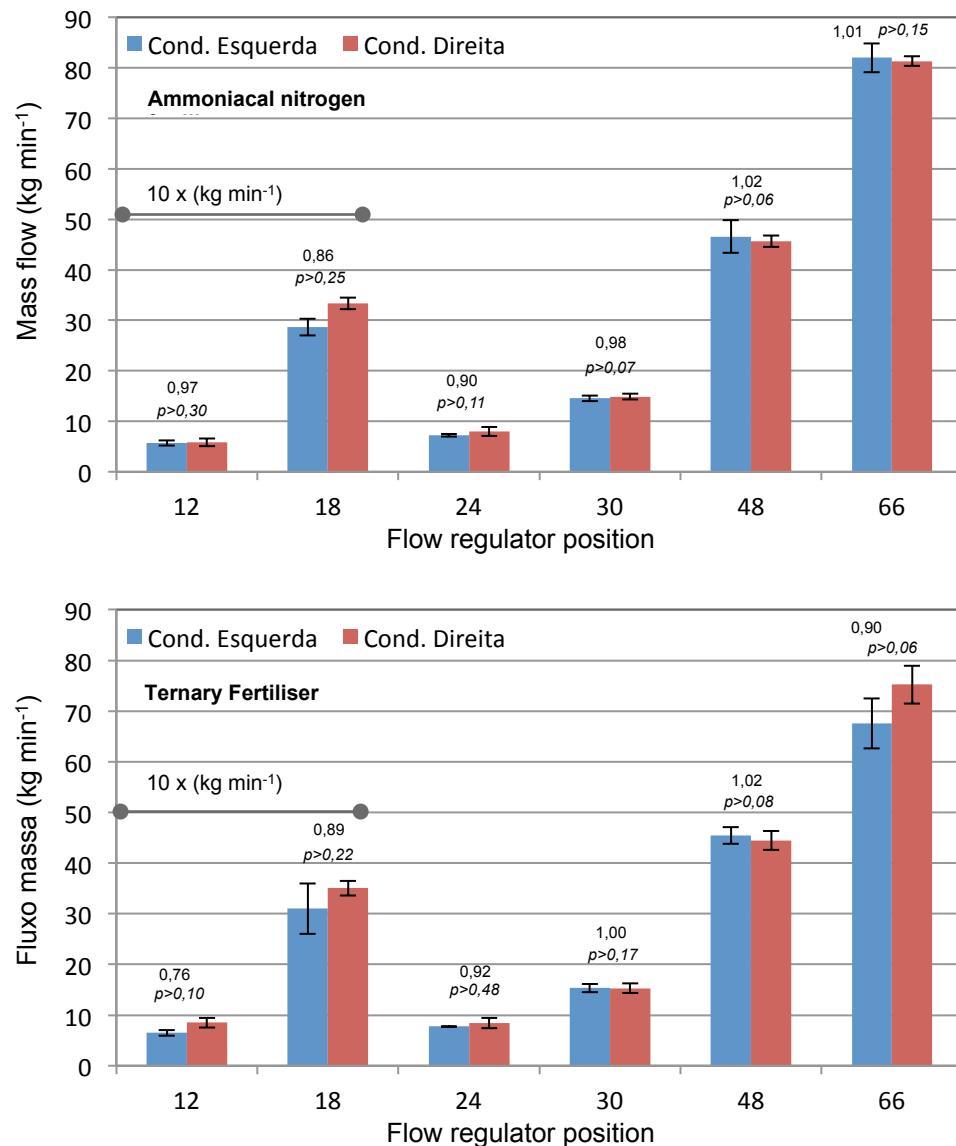

Figure 2. Comparison of the mass flow on each of the spreader conduits for different regulation scale positions and for the two fertilisers tested. The vertical bars represent the mean confidence interval for the mean (95%). The initial values at the top of the columns represent the ratio between the mass flow between conduits (Left/Right). The second values at the top of the columns represent the probability ( $p$ ) associated with the test  $t_{Student}$  for paired samples. It is considered that there are statistically significant differences between the flow from the conduits when  $p < 0.05$ . To allow the graphic display on just one scale, the mass flow for positions 12 and 18 has been augmented by 10x.

## 2. SPREADER FERTILISER FLOW

Table 2 shows – for the various scale positions – the confidence interval for the mean and the variation coefficient for fertiliser flow of the ‘commercial version’ of the spreader, obtained by adding up the mean flow of the repetitions from the left-hand conduit and the right-hand conduit. The statistical indicators were calculated by means of 6 repetitions (3 + 3).

Table 2. Comparison of the confidence interval for the mean and the variation coefficient of the mass flow of the fertilisers tested

Scale Position	Nitro Fertiliser		Ternary Fertiliser		Nitro/Tern
	Kg min <sup>-1</sup>	Cv (%)**)	Kg min <sup>-1</sup>	Cv (%)**)	Ratio
12	1,2 ± 0,06*	4,5	1,5 ± 0,14*	8,4	0,77
18	6,2 ± 0,32	4,5	6,6 ± 0,41	5,5	0,94
24	15,1 ± 0,75	4,4	16,1 ± 0,76	4,2	0,94
30	29,5 ± 0,56	1,7	30,6 ± 0,78	2,3	0,96
48	92,3 ± 2,23	2,1	89,9 ± 1,69	1,7	1,03
66	163,3 ± 1,94	1,0	142,8 ± 6,16	3,8	1,14

\* Confidence interval for the mean 95% of 6 (3 + 3) repetitions.

\*\* Variation coefficient for the 6 (3 + 3) repetitions.

In around 83% (10/12) of situations the variation coefficients are lower than 5%, demonstrating high flow uniformity between repetitions. These values are of paramount importance when evaluating the high reproducibility of the results obtained.

#### IV. DENSITY TABLES FOR FERTILISER APPLIED

The fertiliser flow was determined for the following main flow scale positions: 12, 18, 24, 30, 48 and 66. The fertiliser flow estimate for the other positions (main and intermediate) of the flow adjustment scale was obtained by estimating a regression model (Fig 3) between the observed fertiliser low values and the flow adjustment scale position (positions 12, 18, 24, 30, 48 and positions 66).

Spread fertiliser density (kg ha<sup>-1</sup>) was calculated using the equation below:

$$Q = \frac{600 \times F}{V \times L} \text{ where:}$$

- Q (kg ha<sup>-1</sup>) – fertiliser density;
- F (kg min<sup>-1</sup>) – mass flow;
- V (km h<sup>-1</sup>) – rate of advance;
- L (m) – working width.

Based on this equation, for each of the fertilisers tested the fertiliser density (kg ha<sup>-1</sup>) was calculated for 23 flow scale positions in factorial combination with 5 rates of advance (1, 2, 5, 8 and 10 km h<sup>-1</sup>) and 5 working widths (12, 15, 18, 21 and 24 metres) – tables 3 and 4.

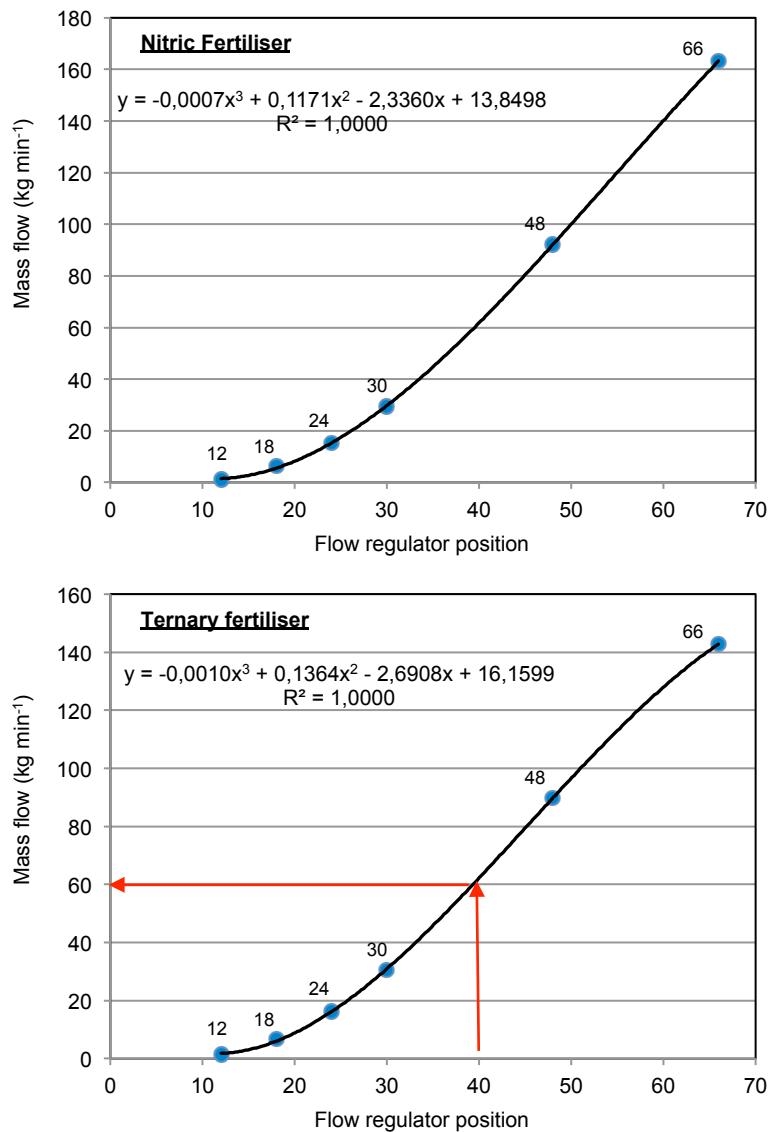

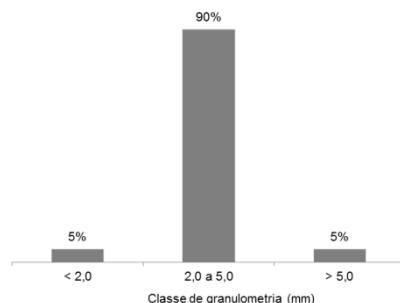

Figure 3. Regression model between the scale position and the corresponding mass flow for each of the fertilisers tested. Example of estimated mass flow for position 40 of the flow scale (position not included in the tests).

Table 3. Ammoniacal nitrogen fertiliser density for different rates of advance in factorial combination with the working width and the flow scale position of the Rocha KC RD 1000 spreader.
